
R2

version 2.6 (November 2010)

Andrew Binley
Lancaster University
November, 2010

Changes to R2 from v2.5

Version 1.3a now outputs results (resistivity, log10 resistivity, sensitivity map, electrode coordinates) in vtk format, allowing easy visualisation with ParaView (which can be downloaded from <http://www.paraview.org/paraview/resources/software.html>). See also http://www.vtk.org/Wiki/The_ParaView_Tutorial for a tutorial on ParaView.

This readme now contains a list of common user errors, which may be helpful for new users.

A 64bit version, R2(x64).exe, is provided in the package, along with the 32bit version (R2.exe).

Computer requirements for R2 v2.6

In this release two versions have been compiled for the Windows environment, one of which account for processor-specific architecture. Users requiring a version compiled for other processors should contact the author.

Introduction to *R2* v2.6

NOTE 1: *all input files should be prepared with a text editor. [I prefer to use TextPad (www.textpad.com) because it allows much greater editing facilities although any text editor will work]. It is important that you do not include tabs in the files. These are often inserted if you copy and paste from Excel, for example. You should convert these tabs to spaces (TextPad will allow you to set this up to happen automatically).*

NOTE 2: *You will be able to run **R2** by double clicking the executable. However, if the program stops abruptly (for example, due to an error in the input file or if you are trying to run an executable compiled for a different processor architecture) then you will not see any error message on the screen since the window will disappear. Therefore, it is advisable to run **R2** from the Command Prompt (just run CMD from the Start Menu – you may need to move your working directory and run **R2** from there).*

R2 is a forward/inverse solution for 3D or 2D current flow in a quadrilateral or triangular mesh. **R2** requires at least two data files: **R2.in** and **protocol.dat**. If a triangular mesh is used then an additional input file – mesh.dat – is required.

R2.in contains information on the geometry of the problem to be solved. **protocol.dat** contains the measurement

The mesh is made up of a set of elements. Parameters (for the inverse solution) are made up of one or more elements. Electrodes are specified at node points. These are the corners of the elements. The boundary conditions along all four boundaries of the mesh are Neumann conditions (zero flux) and therefore if you are investigating a half space you must extend left, right and lower boundaries of the mesh to some distance away from the area of investigation (typically 10 to 20 times the distance).

The mesh can be made up of either quadrilateral elements or triangular elements.

The current version will work with the following problem size limits:

- Quadrilateral finite element mesh size no larger than 500 nodes in the horizontal or vertical directions;
- The total number of nodes in the mesh is not greater than 40,000;
- The total number of elements in the mesh is not greater than 30,000;
- No more than 200 unique electrode sites;
- No more than 5000 measurements;
- No more than 30,000 parameters

For a version to work on a larger problem contact the author.

Input specification for *R2* v2.6

R2 will output a number of files:

- **R2.out** which will contain main log of execution.
- **electrodes.dat** contains the coordinates of the electrodes.

If the problem to be run is a forward model then **R2** will output:

- **R2_forward.dat** which will contain the forward model for the electrode configuration in protocol.dat. The format of **R2_forward.dat** is the same as **protocol.dat** but with 2 extra columns: the first contains the calculated resistances and the second contains the calculated apparent resistivities.
- **forward_model.dat** which will contain the resistivity distribution for your forward model (i.e. what you specified in the input for **R2**). Note that the format of these will be the same as described below for inverse mode.
- **forward_model.vtk** as above but vtk format (allowing plotting in ParaView, for example).

If the problem to be run is an inverse model then **R2** will output:

- **f001_res.dat** which will contain the resistivity result of the inverse solution. f001_res.dat will contain four columns: x, y, resis, log10(resis), where x,y are coordinates at centroid of each element and resis is the resistivity in that element and log10(resis) is log₁₀ of the resistivity value. The format is setup to work directly with Surfer.
- **f001_err.dat** will contain nine columns. In the first column is the normalised data misfit, the second column contains the observed data recorded as an apparent resistivity, the third column contains the equivalent apparent resistivities for the computed model, the fourth column shows the original data weight (i.e. data standard deviation in same units as data), the fifth column is the final data weight, the fifth columns shows a "1" if any weights have been changed during the inversion, otherwise a "0" will appear, the sixth to ninth columns show the electrode numbers.
- if you select resolution matrix calculation then **f001_rad.dat** will contain the diagonal of the resolution matrix for all elements. A value close to 1 indicates that the parameter for that element can be resolved perfectly, a value close to 0 indicates that the parameter cannot be resolved at all. The format is the same as **f001_res.dat**.
- if you select sensitivity map calculation then **f001_sen.dat** which will contain the diagonal of the matrix $[J^T W^T W J]$ which gives an idea of the mesh sensitivity coverage. You will get a value for all elements. High values indicate high sensitivity to data, low values indicate poor sensitivity. Plot on a log scale. The format is the same as **f001_res.dat**.
- **f001_res.vtk** will contain resistivity, log10 resistivity, log10 sensitivity (if selected) and log10 resolution (if selected) in vtk format (allowing plotting in ParaView, for example).
- If you have more than one dataset in protocol.dat (see later) then the files **f001_res.dat**, **f002_res.dat**, **f003_res.dat**, etc will be created. Similarly a set of **_err.dat**, **_rad.dat** and/or **_sen.dat** files will be output.
- The output **f001_res.dat** is made at convergence, however, sometimes it is useful to look at the resistivity image at various stages in the iterative process. For all iterations prior to the final iteration a file **f001.XXX_res.dat** will be output, where XXX is 001, 002, 003, etc for the first, second, third, etc iterations. The format of this file is the same as **f001_res.dat**. If multiple datasets appear in protocol.dat then corresponding output files will be created. For example, **f003.005_res.dat** will be the fifth iteration of the inversion of the third dataset in protocol.dat.

In addition **R2** will output:

- **electrodes.dat** , which contains the co-ordinates of the electrodes. The values are in three columns: x,y.
- **electrodes.vtk** contains the co-ordinates of the electrodes in vtk format. The values are in three columns: x,y,z (the latter being set to zero). Use this file if you are working with Paraview to look at the resistivity images. Once you have opened the electrodes.vtk file in Paraview you select "apply" then you select the "Glyph" icon; this allows you to plot the electrodes as small spheres (or other objects).

Details of R2.in

Line1: (Char*80) **header**

where **header** is a title of up to 80 characters

Line 2: (2 Int, Real, 2 Int) **job_type**, **mesh_type**, **flux_type**, **singular_type**, **res_matrix**

where **job_type** is 0 for forward solution only or 1 for inverse solution; **mesh_type** is 3 for triangular mesh or 4 for a regular quadrilateral mesh or 5 for a more generalised quadrilateral mesh; **flux_type** is 2.0 for 2D current flow (i.e. line electrodes) or 3.0 (usual mode) for fully 3D current flow; **singular_type** is 1 if singularity removal is to be applied (otherwise 0). Note that singularity removal can only be applied is (a) the boundaries are infinite and (b) the $y=0$ plane defines the upper boundary; **res_matrix** is 1 if a 'sensitivity' matrix is required for the converged solution. This matrix is not the Jacobian but is the diagonal of $[J^T W^T W J]$ which gives an idea of the mesh sensitivity (see equation 5.20 of Binley and Kemna, 2005). One value is stored for each finite element in the mesh. High values indicate high sensitivity, low values indicate poor sensitivity. Plot on a log scale. Set **res_matrix** to 2 if the true resolution matrix is computed for a converged solution and the diagonal is stored (see equation 5.18 of Binley and Kemna, 2005), note that this calculation is more time consuming than the 'sensitivity matrix' option. If neither sensitivity map or resolution matrix is required then set **res_matrix** to 0

If **mesh_type** is 3 then a triangular mesh is to be used. This allows much greater flexibility of defining geometry but requires creation of a finite element mesh. The file **mesh.dat** must be supplied which contains the mesh details including node coordinates and element indices (see details later).

If (**mesh_type** = 4) then a regular quadrilateral mesh is to be used and the following are read:

Line 3: (2 Int) **numnp_x**, **numnp_y**

where **numnp_x** is number of nodes in the x direction (horizontal) and **numnp_y** is the number of nodes in the y (vertical) direction

Line 4: (numnp_x Real) **xx**

where **xx** is an array containing x coordinates of each of **numnp_x** node columns

Line 5: (numnp_x Real) **topog**

where **topog** is an array containing elevations of each of **numnp_x** node columns. If the topography is flat then set **topog** to zero for all values.

Line 6: (numnp_y Real) `yy`

where `yy` is an array containing y coordinates of each of `numnp_y` node rows relative to the `topog` array. Set `yy(1)` to zero and the other values to a positive number.

Else if (`mesh_type` = 5) then a more generalised quadrilateral mesh is to be used and the following are read:

Line 7: (2 Int) `numnp_x, numnp_y`

where `numnp_x` is number of nodes in the x direction (horizontal) and `numnp_y` is the number of nodes in the y (vertical) direction

Line 8: (numnp_x Real) `xx`

where `xx` is an array containing x coordinates of each of `numnp_x` node columns

Line 9: (numnp_y Real) `yy`

where `yy` is an array containing y coordinates of each of `numnp_y` node rows for column 1 in the x direction. Set `yy(1)` to zero and the other values to a positive number.

Repeat Line 9 for all `numnp_x` columns.

End if

Note: It is wise to add a carriage returns to break up a long list of input values (in Line 4, 5, 6, 8 and 9, for example). Don't write more than 20 numbers on each line as the compiler doesn't like it.

If (`mesh_type` = 3) then read the following

Line 10: (Real) `scale`

where `scale` is a scaling factor for the mesh co-ordinates. This is usually 1.0 but if a standardised mesh is used, say for a unit circle, then this scaling factor is useful to adjust the mesh for a specific problem. Set `scale=1` if you do not wish to change the coordinates of the mesh defined in `mesh.dat`

End if

Line 11: (Int) `num_regions`

where `num_regions` is number of resistivity regions that will be specified either as starting condition for inverse solution or actual model for forward solution. The term "region" has no significance in the inversion – it is just a means of inputting a non-uniform resistivity as a starting model for inversion or for forward calculation.

If (`num_regions` = 0) then read the following

Line 12: (15*Char) `file_name`

where `file_name` is the name of the file containing the resistivities from a previous inversion (the `_res.dat` file that had been produced). Note that the `file_name` must be no more than

15 characters and there should be no spaces before the file name and no characters in the line after the file name.

Else

Line 13: (2 Int, Real) `elem_1, elem_2, value`

where the resistivity `value` will be assigned for all elements from `elem_1` to `elem_2` (inclusive). Note that for a quadrilateral mesh the elements are numbered down columns first (top to bottom) then along rows (left to right).

Repeat Line 13 for all `num_regions`

End if

NOTE 1: *you must assign all elements a starting value. The number of elements in the mesh is $(numnp_x-1) \times (numnp_y-1)$ for a quadrilateral mesh. All these elements must be assigned a resistivity. Note also that if you assign an element a value, it will overwrite any previous assignment.*

If (`job_type` = 1. i.e. an inverse solution) then read the following

If (`mesh_type` = 4 or 5) then read the following

Line 14: (2 Int) `patch_size_x, patch_size_y`

where `patch_size_x` and `patch_size_y` are the parameter block sizes in the x and y direction, respectively. Note that the number of elements in the x direction must be perfectly divisible by `patch_size_x` and the number of elements in the y direction must be perfectly divisible by `patch_size_y` otherwise set them both to zero.

If (`patch_size_x` = 0) and (`patch_size_y` = 0) then read the following

Line 15: (2 Int) `num_param_x, num_param_y`

where `num_param_x` and `num_param_y` are the number of parameter blocks in the x and y directions

Line 16: (1+`num_param_x` Int) `npxstart, npx(i), i=1,num_param_x`

where `npxstart` is the column number in the mesh where the parameters start; `npx` specifies the number of elements in each parameter block in the x direction

Line 17: (1+`num_param_y` Int) `npystart, npy(i), i=1,num_param_y`

where `npystart` is the row number in the mesh where the parameters start; `npy` specifies the number of elements in each parameter block in the y direction

End if

End if

Line 18: (Int) `inverse_type`

where `inverse_type` is 0 for pseudo-Marquardt solution or 1 for regularised solution with linear filter (usual mode) or 2 for regularised type with quadratic filter or 3 for qualitative solution or 4 for blocked linear regularised type (see also line 24). Note that the blocking defined here is only for a quadrilateral mesh – for blocking within a triangular mesh see the details for preparing `mesh.dat` later.

if (`inverse_type` = 3) then

Line 19: (Int) `qual_ratio`

where `qual_ratio` is 0 for qualitative comparison with forward solution, i.e. only when one observed data set is available, or `qual_ratio` is 1 if the observed data in `protocol.dat` contains a ratio of two datasets

Line 20: (2 Real) `rho_min`, `rho_max`

where `rho_min` and `rho_max` are the minimum and maximum observed apparent resistivity to be used

Else

NOTE: the following line input is different to v2.4 and older versions of R2

Line 21: (2 Int) `data_type`, `reg_mode`

where `data_type` is 0 for true data based inversion or 1 for log data based. Note that the latter should improve convergence but may not work for internal electrodes (e.g. borehole type) where the polarity can change due to resistivity distributions `reg_mode` is 0 for normal regularisation; or 1 if you want to include regularisation relative to your starting resistivity (this is whatever you have set in input lines 11 to 13); or 2 if you wish to regularise relative to a previous dataset using the "Difference inversion" of LaBrecque and Yang (2000). If you select `reg_mode`=1 then Line 22 will require a regularisation parameter `alpha_s`. If you select `reg_mode`=2 then `protocol.dat` must contain an extra column (see below) with the reference dataset. In addition, your starting model (see Line 12) should be the inverse model for this reference dataset (i.e. you need to invert the reference dataset before running the time-lapse inversion). Also note that if you select `reg_mode`=2 then `data_type` is automatically set to 0 irrespective of what was entered in Line 21.

NOTE: the following line input is different to v2.4 and older versions of R2

if ((`reg_mode` = 0) or (`reg_mode` = 2)) then

Line 22: (Real, 2 Int, Real) `tolerance`, `max_iterations`, `error_mod`, `alpha_aniso`

Else

Line 22: (Real, 2 Int, 2 Real) `tolerance`, `max_iterations`, `error_mod`, `alpha_aniso`, `alpha_s`

End if

where `tolerance` is desired misfit (usually 1.0); `max_iterations` is the maximum number of iterations; `error_mod` is 0 if you wish to preserve the data weights, 1 or 2 if you wish the inversion to update the weights as the inversion progresses based on how good a fit each data point makes. `error_mod=2` is recommended. Note that no weights will be increased. The smoothing factor used in the code (`alpha`) is searched for at each iteration. The search is done over a range of steps in `alpha`, the number of steps is `num_alpha_steps`. `alpha_aniso` is the anisotropy of the smoothing factor, set `alpha_aniso > 1` for smoother horizontal models, `alpha_aniso < 1` for smoother vertical models, or `alpha_aniso=1` for normal (isotropic) regularisation. `alpha_s` is the regularisation to the starting model (if you set `reg_mode = 1` in Line 21). Set `alpha_s` to a high value (e.g. 10) to highly penalise any departure from this starting model. Note that `alpha_s` will stay fixed – if you set it too high then **R2** may not converge. R2.out will report the value of `alpha` used to regularise smoothing within the image – the regularisation relative to a reference model is additional to this. The user may find setting `alpha_s` useful as a comparison of inversions from two runs with difference reference models allows an assessment of the depth of investigation following the approach of Oldenburg and Li (1999).

Line 23: (4 Real) `a_wgt, b_wgt, rho_min, rho_max`

where `a_wgt` and `b_wgt` are error variance model parameters following:

$$\text{var}(R) = (a_wgt * a_wgt) + (b_wgt * b_wgt) * (R * R)$$

where `R` is the resistance measured.

It is advisable to estimate `a_wgt` and `b_wgt` from error checks in the field data (ideally from reciprocal measurements - not measures of repeatability). Typically for surface data `a_wgt` will be about 0.01 ohms and `b_wgt` will be about 0.02 (roughly equivalent to 2% error). Note that if you select `data_type=1` in Line 21 then although the resistance data are transformed into log apparent conductivities the `a_wgt` and `b_wgt` parameters should still reflect the variance of the resistance; `rho_min` and `rho_max` are the minimum and maximum observed apparent resistivity to be used for inversion (use large extremes if you want all data to be used). If data are ignored by **R2** because of the apparent resistivity limits then these will be reported individually in R2.log. Note that the apparent resistivity calculations assume that you have set the ground surface to `Y=0` and that the ground surface is flat. Note also that you can select to include individual errors for each measurement in the data input file `protocol.dat` – to do this `a_wgt` and `b_wgt` should be set to 0.0 – `protocol.dat` will then require an additional column (see later).

Line 24: (num_param_x Int) `param_symbol`

If you have specified blocking of parameters (`inverse_type = 4` in line 18) so that each block type is disconnected from other blocks then the blocks are specified by producing a simple plan of the parameter mesh. You must input for each row of parameters an integer representing the parameters. This is repeated for each row. Make sure that you put a space between each integer. As an example say a mesh with 10 elements in the `y` direction and 12 elements in the `x` direction is set to have a parameter patch size of 2, so in total there are 5 parameters (`x`) by 6 parameters (`y`). If we want to set the bottom two rows of parameters (4 elements) not to be smoothed along with the top four rows (8 elements) then the following could be input:

```
1 1 1 1 1
1 1 1 1 1
```

```
1 1 1 1 1
1 1 1 1 1
2 2 2 2 2
2 2 2 2 2
```

Repeat line 24 for all `num_param_y`

End if

End if

Line 25: (Int) `num_electrodes`

where `num_electrodes` is number of electrodes

If (`mesh_type = 3`) then

Line 26: (2 Int) `j, node`

where `j` is the electrode number and `node` is the node number in the finite element mesh

Else

Line 27: (3 Int) `j, column, row`

where `j` is the electrode number, `column` is the column index for the node the finite element mesh and `row` is the row index for the node in the finite element mesh. The `column` value must be in the range 1 to `numnp_x` and the `row` value must be in the range 1 to `numnp_y`. Both values must be integer values.

End If

Repeat Line 27 for all `num_electrodes`

END OF INPUT FOR R2.in

Details of protocol.dat

protocol.dat contains measurement schedule (and data for inverse if selected)

Line 1: (Int) `num_ind_meas`

where `num_ind_meas` is number of measurements to follow in file

If (`job_type = 1`) then

Line 2: (5 Int, 3 Real) `j, elec(1,k), elec(2,k), elec(3,k), elec(4,k), v_i_ratio, v_i_ratio_0, data_sd`

where `j` is not used (but usually is used as a measurement number); `elec(1,k)` is the electrode number for the P+ electrode; `elec(2,k)` is the electrode number for the P- electrode; `elec(3,k)` is the electrode number for the C+ electrode; `elec(4,k)` is the electrode number for the C- electrode; `v_i_ratio` is measured resistance value (or ratio of two measured values if `inverse_type=2` and `qual_ratio=1` in R2.in); `v_i_ratio_0` is the resistance data for background

case (only read if `reg_mode=2`); `data_sd` is data standard deviation (only read if `a_wgt` and `b_wgt` in line 23 of R2.in are both zero)

Repeat Line 2 for all `num_ind_meas`

Else

Line 3: (5 Int) `j, , elec(1,k), elec(2,k), elec(3,k), elec(4,k)`

where `j` is not used (but usually is used as a measurement number); `elec(1,k)` is the electrode number for the P+ electrode; `elec(2,k)` is the electrode number for the P- electrode; `elec(3,k)` is the electrode number for the C+ electrode; `elec(4,k)` is the electrode number for the C- electrode

Repeat Line 3 for all `num_ind_meas`

End if

You can add as many datasets to the file `protocol.dat`. Just concatenate the datasets into one file. **R2** will continue to read and process data using the settings defined in `R2.in`
END OF INPUT FOR `protocol.dat`

Details of `mesh.dat`

If you are working with a triangular mesh then you must create the mesh and store details of the geometry of the mesh in a file `mesh.dat`. **GMS** and other similar packages have mesh generation tools that are suitable for this purpose. In **GMS** a mesh can be created and 'materials' defined, allowing some zoning of the mesh (to permit blocking at interfaces). Also, a finer mesh can be created to be used as the baseline mesh with a coarser mesh to define the parameters. The simplest mesh consists of an equal number of parameters and elements and one zone. More complex arrangements allow for grouping of elements into parameters and multiple zones. Regularisation is not applied at the interface of zones.

Line 1: (2 Int) `numel, numnp`

Where `numel` is the number of triangle elements and `numnp` is the number of nodes.

Line 2: (6 Int) `n, index(1,n), index(2,n), index(3,n), param(n), zone(n)`

Where `n` is the element number; `index(1,n)`, `index(2,n)` and `index(3,n)` are the node numbers of the element, numbered in a counter-clockwise direction; `param(n)` is the parameter number of the element (to make every element a parameter then make this value equal to the element number); `zone(n)` is the zone number for element `n`. To have one zone make `zone(n)` equal to 1 for all elements. Zones must be connected elements. Parameters cannot occupy more than one zone. Note also, to make an parameter fixed to the starting resistivity, set `param(n)` to zero.

Repeat line 2 for all `numel` elements.

Line 3: (Int, 2 Real) `n, x(n), y(n)`

Where `n` is the node number; `x(n)`, `y(n)` are the coordinates of node `n`.

Repeat line 3 for all `numnp` nodes.
END OF INPUT FOR `mesh.dat`

Examples

The folder "Examples" contains a number of worked examples of **R2** to illustrate how to setup input files and work with model output.

Surface electrode array 1

The subfolder "Examples/Surface_1/dpdp" contains an example synthetic model of a surface electrode array using a dipole-dipole measurement scheme. The example is taken from Binley and Kemna (2005). For this problem 25 electrodes are positioned at 2m spacing on a flat surface of a half space. The electrodes are numbered 1 to 25 from left to right. A forward model is setup to determine the measured transfer resistances for a dipole-dipole scheme with 117 measurements. The resistivity model is shown in Figure 1. A small target with resistivity $10 \Omega\text{m}$ lies within a $100 \Omega\text{m}$ half space: positioned vertically between depths 1m and 4m and horizontally between 14m and 16m.

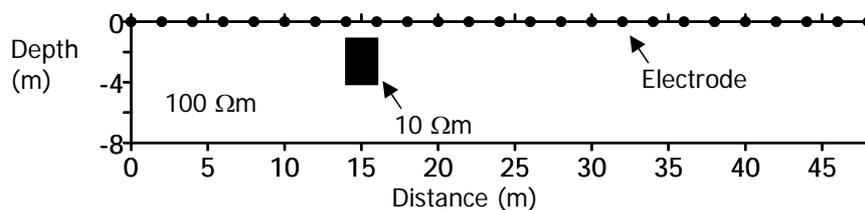

Figure 1: Definition of synthetic model for surface array 1 problem

The subfolder "Examples/Surface_1/dpdp/Forward" contains the protocol.dat file for the forward problem. Also contained in the folder is the file R2.in which defines the geometry and resistivity model. Since the model is a half space the finite element mesh must extend significantly away from the region of investigation (horizontally and vertically downwards). The mesh developed consists of 225 node columns and 49 node rows (i.e. 11025 nodes, 10752 elements). The file R2.in shows how the mesh is designed to get progressively coarser away from the region of study. Note that the coordinates of the mesh have been set so that electrode 1 is at (0,0) for this problem. In the mesh electrode 1 is located at node column 17 (i.e. there are 16 elements to the left of the electrode array to represent an infinite boundary condition to the left). For this example 8 elements are placed between electrodes and so node 2 is at node column 25, node 3 is at column 33, etc. Since the electrodes are located on the ground surface the row node for all electrodes is 1. All the electrode positions are assigned in R2.in. The file also assigns the resistivity for all elements. For this problem it is done by defining the resistivity of 9 congruent blocks of elements. First all elements in the mesh are set to $100 \Omega\text{m}$ and then 8 columns of vertically adjacent elements are defined to set the $10 \Omega\text{m}$ anomaly (remember that the elements are numbered vertically then horizontally).

When **R2** is run the output files are:

R2.out, which contains the main log of execution

electrodes.dat, which contains the electrode co-ordinates

R2_forward.dat, which contains the forward model, i.e. the 117 transfer resistances. Note that the apparent resistivity for each of the 117 measurements is also stored.

forward_model.dat, which contains the co-ordinates of the centroid of each finite element in the mesh, the resistivity of each finite element along with the logarithm (to base 10) of the resistivity. This file is useful for checking if the resistivities were defined correctly in R2.in

In Binley and Kemna (2005) the same forward model is presented in pseudo section format.

The subfolder "Surface_1/dpdp/Inverse" contains files for running the inversion of the transfer resistances determined above. For this a uniform starting resistivity of $100 \Omega\text{m}$ is defined in the file

R2.in. The 'data' to be inverted is stored in file protocol.dat: here the values are simply the transfer resistances that appeared in the R2_forward.dat file described earlier.

For the inverse problem we have used a patch_size of 4 in both x and y directions, i.e. each inverse parameter is a 4 by 4 block of finite elements.

When **R2** is run in this case the output files are:

- R2.out, which contains the main log of execution;
- electrodes.dat, which contains the electrode co-ordinates;
- f001_res.dat, which contains the computed resistivity (and log10 resistivity) for each finite element (in the entire mesh – not just the region of interest);
- f001_err.dat, which contains the misfit for each of the 117 measurements;
- f001_sen.dat, which contains the sensitivity map computed using equation 5.20 in Binley and Kemna (2005);
- f001.001_res.dat, which contains the computed resistivity (and log10 resistivity) for each finite element after the first iteration. Note that the inversion converged after 2 iterations for this problem and so this is the only intermediate solution.

Figure 2 shows the results of the inversion (compare with Fig 5.8 of Binley and Kemna(2005)). This is an image map of the results in f001_res.dat (x and y in columns 1 and 2 and logarithm of resistivity in column 4). Note that only the region within the electrode array and to a depth of 8m has been plotted.

In Figure 3 the sensitivity map is shown (res_matrix in line 2 of R2.in is set to 1). The values are computed with the equation 5.20 of Binley and Kemna (2005). High values indicate areas of high measurement sensitivity.

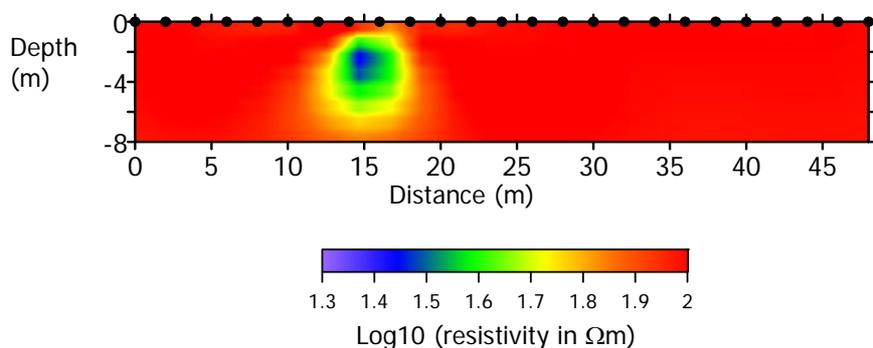

Figure 2: Inverse model for surface array 1 problem with dp-dp array

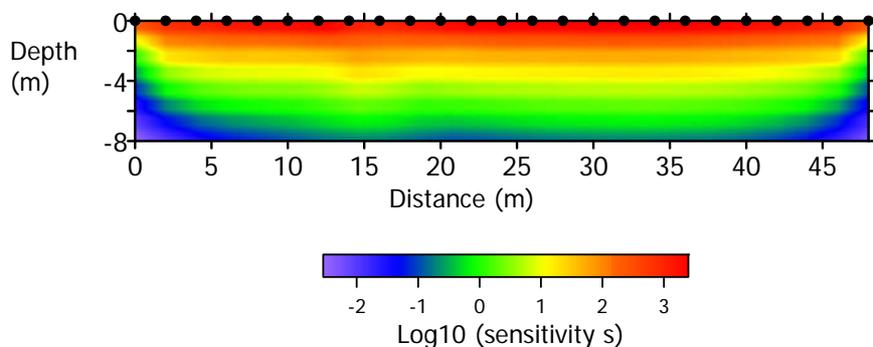

Figure 3: Sensitivity map for inverse model for surface array 1 problem with dp-dp array

Had the problem been run with [res_matrix](#) in line 2 of R2.in set to 2 then the diagonal of the resolution matrix would have been computed. This is useful for comparing models and measurement schemes. In Figure 4 the map of the resolution matrix diagonal is shown. Values

should be ideally equal to 1 (logarithm equal to 0) – values less than this indicate the effect of smoothing on the parameter value (influence of adjacent parameter values). The map of the diagonal of the resolution matrix is very useful for determining a suitable filter for displaying results.

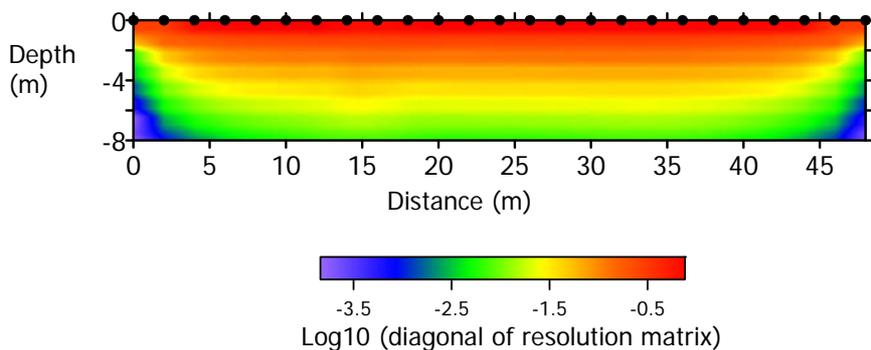

Figure 4: Diagonal of resolution matrix for inverse model for surface array 1 problem with dp-dp array

The subfolder "Surface_1/Wenner/Forward" contains files for running a forward model for the same problem but using a Wenner configuration (see figure 5.7 of Binley and Kemna(2005) for the pseudo section. The subfolder "Surface_1/Wenner/Inverse" contains the files for running the inverse model. Figure 5 shows the resulting model. Figure 6 shows the diagonal of the resolution matrix for this solution, illustrating a weaker resolution in comparison to the dipole-dipole array (c.f. Figure 4),

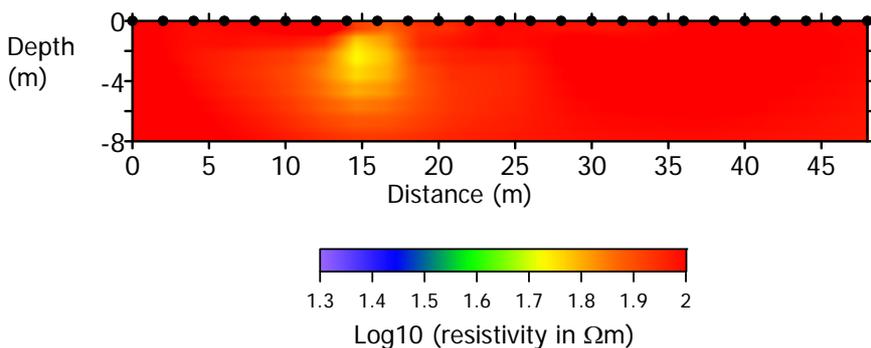

Figure 5: Inverse model for surface array 1 problem with Wenner array

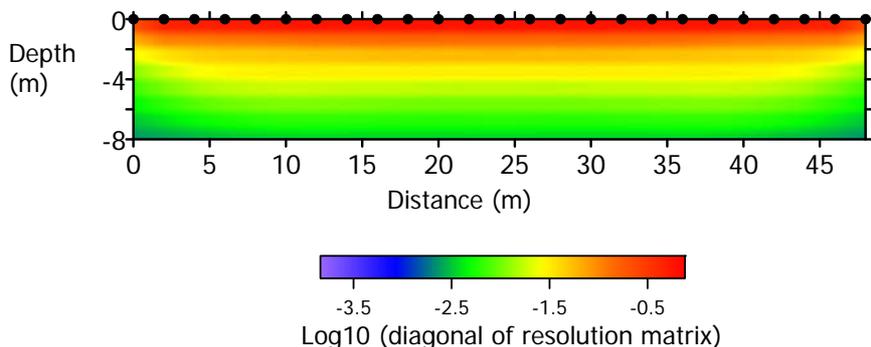

Figure 6: Diagonal of resolution matrix for inverse model for surface array 1 problem with Wenner array

Surface electrode array 2

The subfolder "Examples/Surface_2/dpdp" contains an example similar to the previous case but with varying surface topography. Here the ground surface slopes from 0m at electrode 1 to 4.8m at electrode 25 (see Figure 7). The file R2.in is now different for the forward and inverse model runs through the addition of topography data. Figure 8 shows the inverse solution for this case.

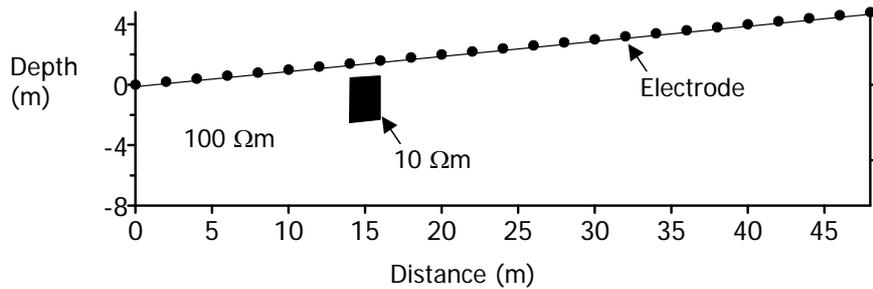

Figure 7: Definition of synthetic model for surface array 2 problem

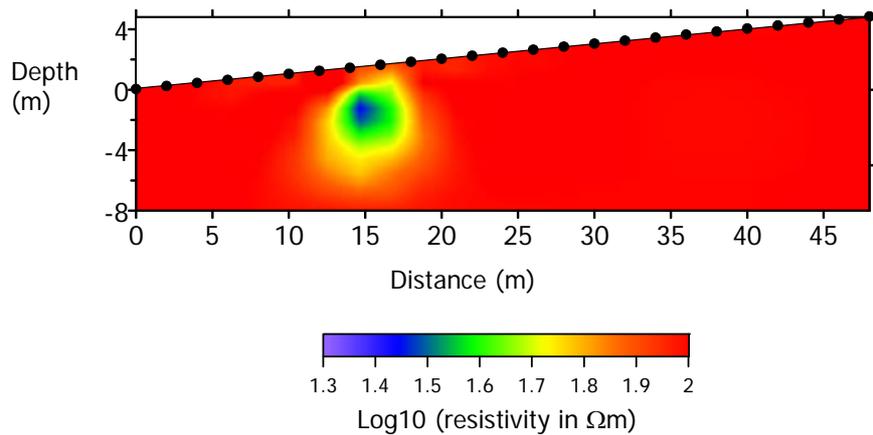

Figure 8: Inverse model for surface array 2 problem with dipole-dipole array

Surface electrode array 3

Occasionally it is useful to fix resistivity values within the mesh. This is particularly useful for time lapse imaging where we wish to focus on changes within a particular part of the mesh. In **R2** this can be achieved with a quadrilateral mesh by defining left, right, upper and lower limits of the parameter zone (see Line 16 and line 17 definitions for R2.in). To illustrate this we invert data from a previous example but constrain the parameter zone to a smaller region of the mesh.

The subfolder "Examples/Surface_3/dpdp" contains an example similar to the Surface array 1 example but this time the inverse model is defined so that not all elements are parameters. The forward model used for generating the data file (protocol.dat) is that from Figure 1, i.e. in "Examples/Surface_1/dpdp/Forward".

For this example we use a patch_size of zero in the x and y directions and then define the location of the zone to be parameterised. In R2.in a patch of 4 elements per parameter is defined in the horizontal direction starting at element 1. All elements are grouped into parameters in the horizontal and thus there are 56 patches of 4 elements declared (a total of 224 elements). In the vertical we define the parameter zone to be from 1m to 6m depth and a patch size of 2 elements is used (10 parameters in total corresponding to the 20 elements). The starting element for the parameterisation in the vertical is 5 (since the first four elements cover the first 1m in this case). Note that the resistivity of any element that is not declared to contribute to a parameter remains unchanged from the starting value (in this case 100 Ωm).

Figure 9 shows the resultant inverse model. The sharp boundaries (in the vertical) at 1m and 6m are a result of the constrained parameter zone (there is no smoothing over the boundaries).

Note that if you restrict the parameter zone too much then convergence of the solution may be problematic (since you will be reducing the degrees of freedom of the inverse solution).

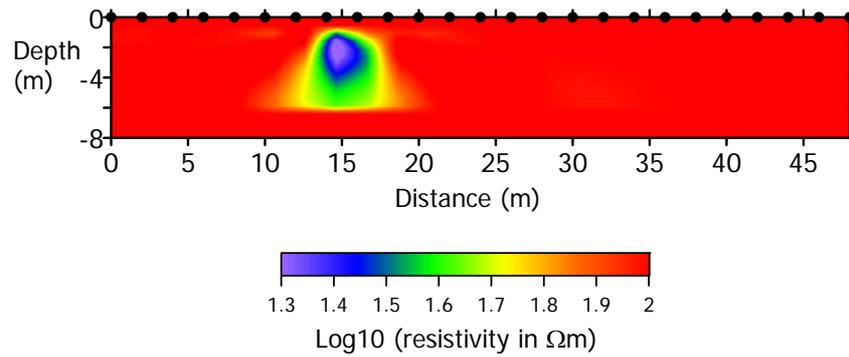

Figure 9: Inverse model for surface array 3 problem

Surface electrode array 4

The subfolder “Examples/Surface_4/dpdp” contains an example similar to the Surface array 1 example but this time the smoothing is set to be anisotropic. For this case the smoothing is exaggerated in the vertical by setting `alpha_aniso` in Line 22 of **R2.in** to 0.1 (10 times more smoothing in the vertical). Figure 10 shows the resultant inversion (c.f. Figure 2 with isotropic smoothing).

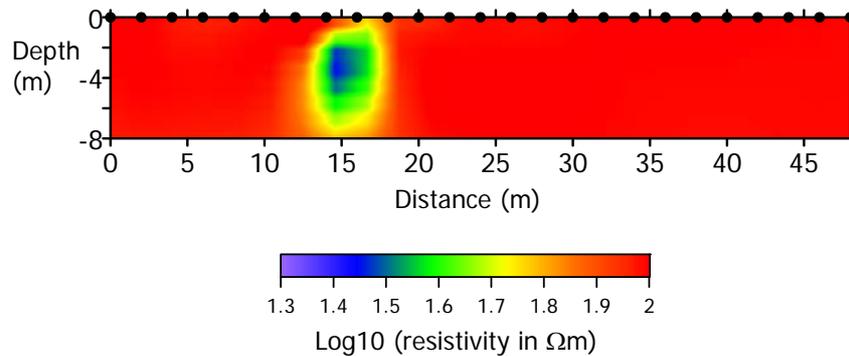

Figure 10: Inverse model for surface array 4 problem

Surface electrode array 5

The examples so far have used a simple quadrilateral mesh definition. For the surface array 2 example the mesh was distorted by changing the topography of the upper surface of the mesh. In this example we illustrate how to change the mesh in a more flexible manner. By setting `mesh_type` to 5 in Line 2 of **R2.in** we can specify the row coordinates for every column of the mesh. This requires more input information than the previous examples but gives much greater flexibility.

The subfolder “Examples/Surface_5/dpdp/Forward” contains a forward modelling example similar to the Surface array 1 example but in this case a zone of low resistivity lies just below the ground surface and varies in thickness from 0.5m at electrode 1 to 1m at electrode 25. In addition, the electrodes are located in this example at the bottom of this conductive zone. Such a model may be representative of electrical imaging using electrodes placed at the bed of a stream (the conductive zone representing the stream).

To setup this forward model the 49 row coordinates are defined for all 225 column positions. In addition, **R2.in** must also contain the definition of more groups of elements than before to represent the conductive zone (remember that the zones are defined as groups of congruent elements and since the elements are numbered in the vertical then we must define 224 such groups for this problem, in addition to the rest of the region, i.e. 225 groups in all).

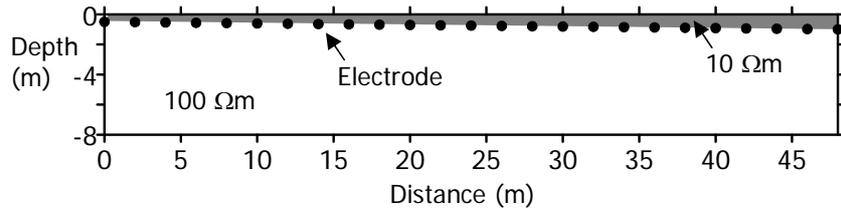

Figure 11: Forward model for surface array 5 problem

Surface electrode array 6

The subfolder “Examples/Surface_5” contains three examples illustrating the use of a reference resistivity model. The examples use the dipole-dipole forward model from Surface electrode array 1 but invert three difference cases with `reg_mode` set to 1 (see line 21 of R2.in).

In case_01 we set α_s to 10 with a resistivity background (starting model or reference model) equal to a uniform $\rho_{\text{back}}=100\Omega\text{m}$. The results are shown in Figure 12a. The result is similar to that shown in Figure 2 (no regularisation relative to a reference model).

In case_02 we set α_s to 50 with a uniform $\rho_{\text{back}}=100\Omega\text{m}$. The results are shown in Figure 12b. The target recovery is now weaker as the inversion applies more penalty to deviation from $100\Omega\text{m}$.

In case_03 we set α_s to 10 with a uniform $\rho_{\text{back}}=50\Omega\text{m}$. The results are shown in Figure 12c. Recalling that the background resistivity in the forward model is $100\Omega\text{m}$, Figure 12c illustrates the zone over which the measurements have sensitivity – the lower left and right regions are clearly not influenced by the measurements in this case (which is consistent with the resolution matrix in Figure 4).

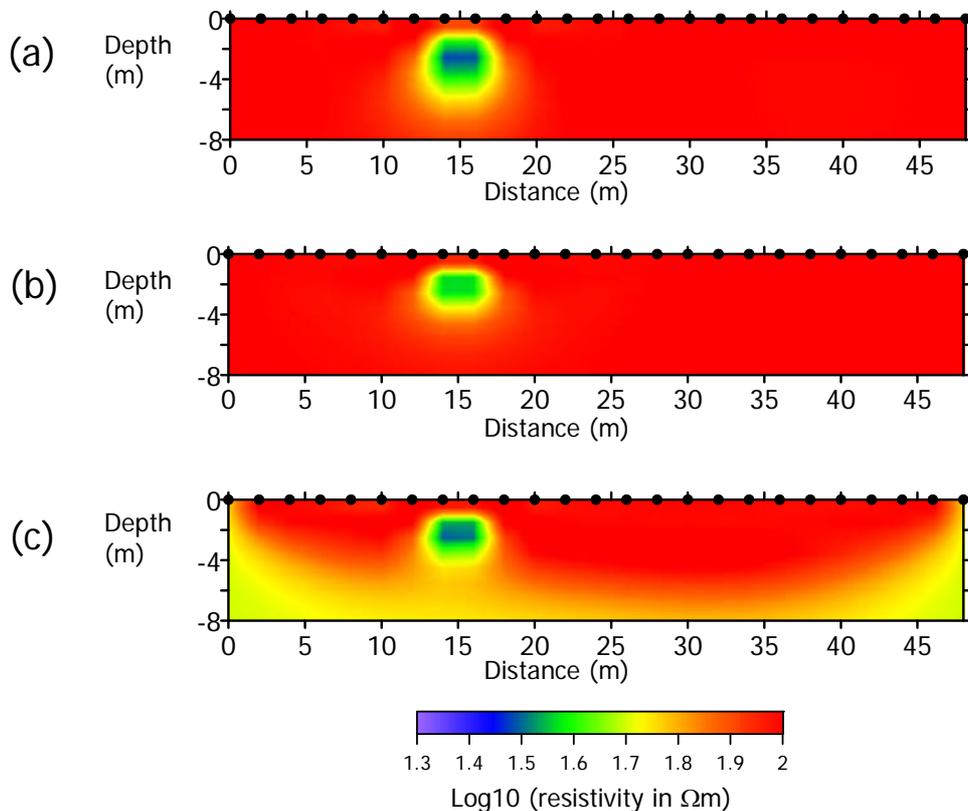

Figure 12: Surface array 6 – regularising relative to a reference resistivity model.
 (a) $\alpha_s=10$, $\rho_{\text{back}}=100\Omega\text{m}$. (b) $\alpha_s=50$, $\rho_{\text{back}}=100\Omega\text{m}$. (c) $\alpha_s=10$, $\rho_{\text{back}}=50\Omega\text{m}$.

We can use these results to assess the depth of investigation (DoI), following the method of Oldenburg and Li (1999). We can compute the value:

$$R(x, y) = \frac{m_1(x, y) - m_2(x, y)}{m_{1,r} - m_{2,r}}$$

Where m_1 are the inversion results in Figure 12a (in log units) using $100\Omega\text{m}$ as a reference and m_2 are the inversion results in Figure 12c (in log units) using $50\Omega\text{m}$ then, $m_{1,r} = \log_{10}(100)$ and $m_{2,r} = \log_{10}(50)$. Figure 13 shows the variation of R . Oldenburg and Li (1999) suggest a reasonable value of $R = 0.1$ or 0.2 as a suitable depth of investigation. Figure 13 shows a contour of $R = 0.2$ to illustrate this.

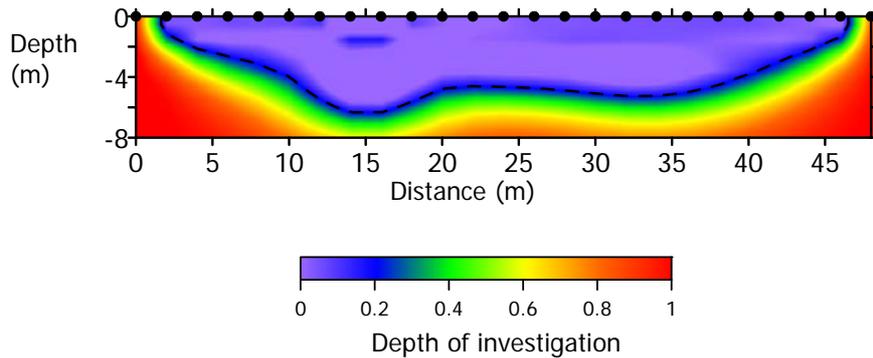

Figure 13: Depth of investigation for Surface array 6 problem.

Cross borehole array

The subfolder “Examples\Xbh” contains forward and inverse models for two cross borehole examples illustrated in Binley and Kemna (2005). The first case considered here is included in “Examples\Xbh\8m_skip7”. In this case measurements are made between two boreholes 8m apart, as illustrated in Figure 13. As in previous examples a zone with resistivity $10\Omega\text{m}$ is embedded in the $100\Omega\text{m}$ half space. The measurement scheme used is a “skip 7”: dipole – dipole with 7 electrode in between each current and potential electrode pair (see the protocol.dat file).

The forward model input files are included in “Examples\Xbh\8m_skip7\forward” and the inverse model files are in “Examples\Xbh\8m_skip7\inverse”. Figure 14 shows the output of the inverse solution using the forward model as “data”.

The second cross borehole case is for two boreholes 15m apart, as illustrated in Figure 15. The forward model input files are included in “Examples\Xbh\15m_skip7\forward” and the inverse model files are in “Examples\Xbh\15m_skip7\inverse”. Figure 16 shows the output of the inverse solution using the forward model as “data”. The effect of increased spacing of the boreholes on sensitivity of the measurements can be seen by comparing Figures 16 and 14.

Common User Errors

Below is a list of some common user errors that I have encountered. This may be useful for new users.

A common mistake is for a new user to go straight into trying to run an inverse solution without getting a good feeling for the model that is being used. New (and old) users working on new problems should first try run a forward model for a uniform resistivity. This will help sort out any problems with the definition of the mesh, etc. It will also be useful in understanding the quality of the forward model and help judge this against the quality of the data.

If you can, run the code from the command line. You will need to run CMD in Windows and create a DOS window, then move to the correct folder and then type **R2**. Doing it like this help see any errors if the program crashes unexpectedly because of incorrect input.

In the example input files provided there are comments at the end of most lines in the form "<< comment" . Note that these are always at the end of a line. You cannot have these appearing on their own in a line. If you do then **R2** will try read this comment when it is expecting numerical input and simply crash.

The mesh is based on elements and nodes. Lines 3 to 9 are based on nodes, whereas Line 13 is based on elements. It is important to understand the difference and not mix the two.

On Line 22, specifying a tolerance of 1.0 means that you are happy that you have estimated your errors correctly (Line 23). Don't just use the a_wgt and b_wgt values in the example files – spend time to understand the likely errors in your measurements and model.

Setting data_type to 1 in Line 22 means that the data you input will be log transformed, not that you have to supply logged data. Note that you do not need to worry about the sign (polarity) of the data if you select the log data type – **R2** will deal with this.

Setting the minimum and maximum apparent resistivity (Line 23) is only valid if you have a flat surface and an infinite half space problem, otherwise the geometric factors that **R2** will compute will be incorrect.

For a quadrilateral mesh the electrode positions are defined by their column and row positions in the mesh (Line 27). These are not the co-ordinates of the electrodes but their position in the mesh,

In the definition of the input files, each line has been defined in terms of the type of numbers that are required. For example, (Real, 2 Int, 2 Real) means one real number, followed by two integers, followed by two reals. You can substitute integers for reals but bit the other way round. So if the code is expecting an integer and your line entry has 1.3, for example, then the code will crash.

Note that the data in **protocol.dat** should be provided in transfer resistances, NOT apparent resistivities. Also note that the polarity should be retained in the data. It is very wise to check the polarity of your measurements – you can do this by computing the geometric factor for your measurement configuration (provided topographic and non-infinite boundaries are not significant). If you don't know how to compute the geometric factors then you should run a forward model with **R2** for a uniform half space and compare the computed polarities with those in your data. For a surface electrode array your data should be the same polarity as the model, otherwise the measurements will not be included in the inversion. For electrodes not on the surface the polarity can change as the resistivity structure changes in the inversion.
